

The Basel Problem

An impossible sum, a young genius, and a surprise visit from π

A slideSonnet demo

What happens when you add the reciprocals of the perfect squares?

$$\frac{1}{1} + \frac{1}{4} + \frac{1}{9} + \frac{1}{16} + \frac{1}{25} + \cdots$$

In modern notation:

$$\sum_{n=1}^{\infty} \frac{1}{n^2} = ?$$

Pietro Mengoli posed this problem in Bologna in 1650. The sum converges to something near **1.6449...** but *what* is it?

Pietro Mengoli posed this problem in Bologna in 1650. The sum converges to something near **1.6449...** but *what* is it? Even **Jakob Bernoulli** admitted defeat in 1689:

Pietro Mengoli posed this problem in Bologna in 1650. The sum converges to something near **1.6449...** but *what* is it? Even **Jakob Bernoulli** admitted defeat in 1689:

“If anyone finds and communicates to us that which thus far has eluded our efforts, great will be our gratitude.”

The problem stayed open for **85 years**. Then, in 1734 in Saint Petersburg, a young mathematician from Basel named **Leonhard Euler** found the answer.

The problem stayed open for **85 years**. Then, in 1734 in Saint Petersburg, a young mathematician from Basel named **Leonhard Euler** found the answer.

$$\sum_{n=1}^{\infty} \frac{1}{n^2} = \frac{\pi^2}{6}$$

π ? In a sum that has nothing to do with circles?

The Taylor series for sine:

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots$$

The Taylor series for sine:

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots$$

Divide both sides by x :

$$\frac{\sin x}{x} = 1 - \frac{x^2}{6} + \frac{x^4}{120} - \dots$$

The Taylor series for sine:

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots$$

Divide both sides by x :

$$\frac{\sin x}{x} = 1 - \frac{x^2}{6} + \frac{x^4}{120} - \dots$$

The coefficient of x^2 is $-\frac{1}{6}$ — hold onto it.

$\frac{\sin x}{x}$ has zeros at $x = \pm\pi, \pm2\pi, \pm3\pi, \dots$

$\frac{\sin x}{x}$ has zeros at $x = \pm\pi, \pm2\pi, \pm3\pi, \dots$. Euler treated it like a polynomial and factored by its roots:

$$\frac{\sin x}{x} = \left(1 - \frac{x^2}{\pi^2}\right) \left(1 - \frac{x^2}{4\pi^2}\right) \left(1 - \frac{x^2}{9\pi^2}\right) \dots$$

(Justified much later by the Weierstrass factorization theorem, 1876.)

With $a_k = \frac{1}{k^2\pi^2}$, three factors give

$$(1 - a_1x^2)(1 - a_2x^2)(1 - a_3x^2) = 1 - (a_1 + a_2 + a_3)x^2 + \cdots$$

Each x^2 term picks $-a_kx^2$ from *one* factor and 1 from the rest.

$$\prod_{n=1}^{\infty} \left(1 - \frac{x^2}{n^2 \pi^2} \right) = 1 - \left(\frac{1}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{n^2} \right) x^2 + \dots$$

So the x^2 coefficient is $-\frac{1}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{n^2}$.

From the Taylor series: $\frac{\sin x}{x} = 1 - \frac{1}{6}x^2 + \dots$

From the Taylor series: $\frac{\sin x}{x} = 1 - \frac{1}{6}x^2 + \dots$ From the product:

$$\frac{\sin x}{x} = 1 - \frac{1}{\pi^2} \sum \frac{1}{n^2} x^2 + \dots$$

From the Taylor series: $\frac{\sin x}{x} = 1 - \frac{1}{6}x^2 + \dots$ From the product:

$\frac{\sin x}{x} = 1 - \frac{1}{\pi^2} \sum \frac{1}{n^2} x^2 + \dots$ Coefficients must agree:

$$\frac{1}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{n^2} = \frac{1}{6}$$

Multiply both sides by π^2 :

$$1 + \frac{1}{4} + \frac{1}{9} + \frac{1}{16} + \dots = \frac{\pi^2}{6} \approx 1.6449\dots$$

The circle constant was hiding in the sum all along.

Euler's proof was not rigorous by modern standards — but the answer was never in doubt.

Euler's proof was not rigorous by modern standards — but the answer was never in doubt. The sum is $\zeta(2)$, a value of the Riemann zeta function $\zeta(s) = \sum_{n=1}^{\infty} n^{-s}$. Even values are rational multiples of powers of π ; the odd values remain mysterious.

$$1 + \frac{1}{4} + \frac{1}{9} + \frac{1}{16} + \cdots = \frac{\pi^2}{6}$$

- A simple question can hide a profound answer.
- The boldness to treat $\sin x/x$ as a polynomial was the key.
- π connects geometry and number theory in ways we still explore.

Thanks for watching.
